An MRI workup should be done in all three groups of patients: patients with a normal cervical CT and patients with a normal MRI of the head, patients with a normal CT and a low-risk MRI of the cervical spine, and patients with a high-risk MRI of the cervical spine. What are the limitations of MR cervical spine imaging? It is relatively contraindicated in patients with claustrophobia and those with metallic implants, aneurysm clips, nails, or screws in the cervical spine. In these patients, cervical spine imaging should be obtained using computed tomography. What should be the goals of MR cervical spine imaging? The main goal of MR cervical spine imaging is to detect specific abnormalities, such as fractures, rheumatoid arthritis, neuropathy, neoplasm, and infectious processes. In addition, the imaging technique can be used to demonstrate ligamentous injury, which can be associated with neck pain. What is the significance of the modified Dixon imaging technique? It has been shown that contrast-enhanced MR imaging is more sensitive than noncontrast-enhanced MR imaging in detecting spinal metastases. When should the MRI cervical spine imaging be obtained? A routine MRI cervical spine study should be done in patients with neck pain, patients with known neck trauma, patients with suspected cervical spine fracture, and patients with suspected cervical spine infection. It should be delayed for 6 months after completion of treatment for cervical spine infection. When should the noncontrast MRI cervical spine imaging be obtained? In patients with suspected neoplasm or infection of the spine, an MRI cervical spine study is indicated. If the imaging study shows evidence of cord compression, the imaging study should be repeated after 3 weeks and then after 2 to 3 months. When should the contrast MRI cervical spine imaging be obtained? It is indicated in patients with a normal noncontrast cervical spine study 2edc1e01e8
